UVC

Since its finding in 1878, artificially produced UVC has become a staple method of sterilisation – one that is used in hospitals, airplanes, offices, and factories every day. The radiation warps the structure of the virus's genetic material and prevents the viral particles from making more copies of themselves.

Ozone

Ozone is a remarkably versatile and powerful disinfectant, one of the strongest oxidizers known to man.

It is a naturally occurring gas created from oxygen atoms. The oxygen molecule is made up of 2 oxygen atoms. These oxygen molecules are broken into atoms by the corona discharge during lightning storms or by UV light from the sun. Single oxygen atoms cannot exist alone without regrouping back into di-atomic oxygen molecules. During this recombination stage, some atoms will regroup into loosely bonded tri-atomic oxygen to form a new molecule known as Ozone.

Typically viruses are small, independent particles, built of crystals and macromolecules. Unlike bacteria, they multiply only within a host cell. Ozone destroys viruses by diffusing through the protein coat into the nucleic acid core resulting in damage of the viral RNA. Put simply, exposing Corona viruses to sufficient Ozone can result in them being 99% damaged or destroyed.

OXYGEN CONCENTRATOR

The working principle of the oxygen concentrator is to use air as a raw material and after compression and filtration inside the machine, it generates a concentration of oxygen.

The oxygen concentrators use molecular sieves that are made in the USA and have a longer life span than ordinary molecular sieves. The machines are all continuous flow. The units can be connected to ventilators subject to interface – recommended for ventilators is the 10L unit.

Accessories include oxygen nasal tube, filter humidification bottle and a mask.
